

EDTA Chelation Therapy

EDTA Chelation therapy can be an expensive and time intensive process depending on the type of form that is chosen. EDTA IV chelation requires that patients attend 30 to 50 sessions over six months. Each of these sessions is at least three hours long and quite expensive (\$100-\$150 per session). EDTA in suppository form is normally administered 3-4 times per week, but may be cost prohibitive and can take in excess of six months to complete. Chelation pills are less expensive than IV or suppository forms, but have a low absorption rate (5-18%) that requires a longer time frame for the completion of therapy.

Oral Liquid Chelation Therapy

EDTA Chelation is also available in convenient oral form, referred to as liquid chelation. With liquid [oral chelation](#), though, the EDTA solution is mixed into the patient's drinking water and can be taken several times a day. Liquid EDTA [chelation](#) is much less expensive than suppository or IV treatments and has a higher absorption rate than the pill option. Liquid oral chelation therapy can be completed in just six weeks, unlike many of the other chelation options that can take up to six months. For more information on liquid oral EDTA, [contact Cardio Renew](#) at 800-578-1215.
